

Afficionado Coffee Roasters — Sales Trend and Time-Based Performance Analysis

Prepared for review by municipal and state economic development, small-business support, and labor-policy stakeholders | July 2026

Purpose of This Summary

This summary translates a transaction-level analysis of 149,116 point-of-sale records from a three-location New York City small business (Hell's Kitchen, Astoria, and Lower Manhattan) into findings relevant to public-sector interests: local economic activity, small-business resilience, and workforce scheduling. It is intended to inform, not to request any specific government action; it illustrates the kind of evidence-based operating picture that data-driven small businesses can now produce, and the categories of data that could usefully inform city and state economic-development and labor programs.

Headline Figures

\$698,812 Total Revenue (2025)	149,116 Transactions Analyzed	45.8% Revenue from Morning Rush (7–10 AM)	32.9%–33.8% Revenue Spread Across 3 Stores
--	---	--	---

Why This Matters to Government Stakeholders

- Data quality and coverage:** This is a full-year, validated transaction dataset (zero missing values, zero duplicates, zero invalid records) spanning three distinct NYC neighborhoods, offering a rare, granular window into small-business retail activity that complements aggregate city sales-tax or employment statistics.
- Workforce scheduling relevance:** Demand is highly concentrated — 45.8% of daily revenue occurs in a single 7–10 AM window, and 63.2% of revenue occurs within just six of roughly fourteen operating hours. This is directly relevant to jurisdictions with predictive- or fair-scheduling requirements (e.g., New York City's Fair Workweek Law), since it demonstrates the kind of hour-level demand evidence such regulations expect employers to use when setting shift schedules.
- Neighborhood-level economic activity:** Revenue is distributed almost evenly across the three neighborhoods (32.9%–33.8% each), suggesting a replicable small-business model rather than dependence on a single high-traffic corridor — a relevant data point for economic-development offices assessing commercial-corridor health across boroughs.
- Foot-traffic and commercial-corridor indicator:** The business operates on a high-frequency, low-basket-size model (97.8% of transactions are one or two items), consistent with foot-traffic-dependent quick-service retail — a useful indicator for planning around transit access, sidewalk activity, and storefront vacancy in the surrounding commercial districts.

- **Data-sharing consideration:** The underlying dataset lacks a full calendar-date field, which limited the analysis to hour-of-day patterns rather than day-of-week or seasonal trends. Any future public-private data-sharing arrangement (e.g., voluntary aggregated retail-activity reporting to a city economic-development office) should specify date-level granularity from the outset to support that level of analysis.

Findings at a Glance

Metric	Finding
Peak demand window	7:00–10:00 AM ("Morning Rush"); single busiest hour is 10:00 AM
Revenue concentration	63.2% of revenue occurs in 6 of ~14 operating hours (Morning + Lunch Rush)
Store-level balance	Revenue share ranges narrowly from 32.9% to 33.8% across 3 locations
Lowest-activity period	After 7:00 PM; the 8:00 PM window contributes under 0.5% of daily revenue
Dominant product categories	Coffee (38.6% of revenue) and Tea (28.1%) together drive two-thirds of revenue

Implications for Public-Sector Consideration

- **1.** The concentration of demand into narrow daily windows illustrates why small food-and-beverage retailers may need scheduling flexibility during compliance reviews under fair-workweek or predictive-scheduling ordinances, provided that flexibility is grounded in demonstrable, data-backed demand patterns such as those shown here.
- **2.** Even revenue distribution across neighborhoods suggests small multi-location businesses can contribute stable, diversified economic activity across several commercial districts rather than concentrating benefit in one area — relevant context for equitable commercial-corridor investment decisions.
- **3.** The methodology demonstrated here (validation, feature engineering, time-bucket analysis) is a template that other small and mid-sized local businesses could apply to their own point-of-sale data, and could inform any voluntary technical-assistance or data-literacy programs a city or state economic-development office might offer to small businesses.

Scope and Limitations

This analysis is based on private, single-business transaction data voluntarily analyzed for internal operational purposes; it is not a survey of the broader retail sector and should not be generalized beyond this business without independent corroboration. The dataset did not include a full calendar-date field, so day-of-week, weekly, and seasonal trends are outside the scope of this summary. No customer-level, employee-level, or personally identifiable information was used in or is contained within this analysis.

Bottom Line

A rigorous, transaction-level analysis of a three-location NYC small business shows a highly predictable, evidence-backed demand pattern — nearly half of daily revenue in a single morning window — and a balanced, replicable footprint across three distinct neighborhoods. These are the kinds of granular, data-driven operating patterns that can inform labor-policy compliance discussions, commercial-corridor planning, and small-business technical-assistance programs, and this project offers one reproducible example of how a small business can generate that evidence from its own data.
